Methodology Notes & Limitations

Read together with the results above — a backtest is only as credible as the assumptions it discloses.

What this backtest controls for

- Walk-forward screening: at every rebalancing date, only price history available up to that date is used (no look-ahead bias in screening or optimisation).
- Transaction costs: 10 bps one-way, applied on every weight change (entries, exits, rebalancing drift) at each quarterly rebalancing date.
- Stepped risk-free rate: the rate used for Sharpe/Sortino now varies by year (roughly 0% in 2019-21, rising through the 2022-23 hiking cycle) instead of one fixed 3% across the full 2019-2026 period.
- Known delistings: tickers removed from the index due to failure or acquisition during the window (e.g. Wirecard, June 2020) are kept and marked down to a terminal value rather than silently dropped by the data-quality filter.

Known limitations (not yet addressed)

- Residual survivorship bias: the starting universe (~120 tickers) was built from companies that exist today. Index removals not explicitly hard-coded here are still excluded; a fully point-in-time universe needs historical constituent data (e.g. iShares daily holdings files).
- Flat transaction costs: 10 bps is applied to every name; less liquid small/mid-cap constituents likely carry higher real market impact.
- No capacity constraints: position sizing assumes the full notional is tradeable at the closing price, with no slippage beyond the flat cost assumption.
- Single regime: 2019-2026 is dominated by a strong post-COVID bull market; performance has not been isolated across a full bear-market cycle.

Suggested next steps

- Source point-in-time index constituents to remove residual survivorship bias entirely.
- Differentiate transaction cost assumptions by market-cap / liquidity bucket.
- Add a regime-conditional performance breakdown (bull / bear / sideways sub-periods).
